RQ6 | Different output contracts reveal different failure modes

PANEL A | What is measured?

TARGET PAPER: free-text output

Generated item titles → title/catalogue matching

Unmatched or fabricated titles
= textual/catalogue hallucination

LOCAL STUDY: constrained output

Candidate-index JSON → parser + validator

Strict validity and structural failures
= output reliability taxonomy

TEXTUAL HALLUCINATION ≠ STRUCTURAL INVALIDITY • NOT DIRECTLY COMPARABLE

PANEL B | Local candidate-index JSON: structural reliability only

G2 unknown/out-of-candidate: 10 requests (16 index values). G1 duplicate-request count uses parser statuses, not raw violation instances.

High local structural validity does not reproduce the paper's free-text hallucination measure; no causal reduction or cross-protocol rate comparison is inferred.
